Follow the navigation panel link “Les écritures” to inuktitut. The author observes that the syllabary used for the Inuit language, Inuktitut, was created at the end of the 19th Century by James Evans, a Wesleyan missionary, inspired by *stenography*. Originally intended for transcription of the Ojibway language, it was later used for Cree and Inuktitut; only these three languages have been written in this syllabary. Examples of the syllabary are shown in links that can be followed from this page; another alphabet table is shown in the colourlab.com URL.

LCCN K662.I4 I58. From *Computing Reviews*: “The article reports on the progress of an historical study using a computer for statistical analysis. The subject of the study is a

mass of trial depositions of the Knights Templar. The purpose of the project is to find statistical regularities in the large amount of testimony and to create a model for similar studies. The Order of the Knights Templar, founded around 1100, was the first Christian military order. After the Crusades, in the early fourteenth century, 127 articles of accusation were brought against the order, including charges of idolatry, sacrilege, and sodomy. The data being studied are the responses of 900 men to each of 127 accusations. The article details the accusations and the way in which the responses are being coded. The statistical package SAS (Statistical Analysis System) will be used. Examples of the results to be sought are: tallies of guilty/innocent responses, tallies of offenses committed versus seen versus heard about, and correlations between, for example, age and other responses. Depositions that differ markedly from the average response will be identified.”.

They show that for a language <math>L</math> in <math>NP</math> and a string <math>w</math> in <math>L</math>, there exists a probabilistic interactive proof that efficiently demonstrates membership of <math>x</math> in <math>L</math> without conveying additional information. Previously, zero-knowledge proofs were known only for some problems that were in both <math>NP</math> and <math>co\text{-}NP</math>. A preliminary version of this paper appeared in <i>Proc. 27th Ann. IEEE Symp. on Foundations of Computer Science</i>, 1986, under the title “Proofs that yield nothing but their validity and a methodology of cryptographic protocol design.”.</p> <p><b>Gemmell:1994:CIA</b></p> <p>[GN94] Peter Gemmell and Moni Naor. This is the author's Ph.D. dissertation. "Secret-key block ciphers are the subject of this work. The design and security of block ciphers, together with their application in hashing techniques, are considered. In particular, iterated block ciphers that are based on iterating a weak round function several times are considered. Four basic constructions for the round function of an iterated cipher are studied.".

This result assumes that authentication, i.e., the encrypting of messages to make them unforgeable, is not used. With unforgeable messages, they show that the problem is solvable for any  $n \geq t > 0$ , where  $n$  is the total number of processes and  $t$  is the number of faulty processes.

This is the book that introduced the conjecture that numbers of the form  $M(n) = 2^n - 1$  are prime for  $n = 2, 3, 5, 7, 13, 17, 19, 31, 67, 127$ , and 257, but could not test this claim. Euler showed in 1750 that  $M(31)$  is prime. Lucas showed in 1876 that  $M(127)$  is prime. Pervouchine showed in 1883 that  $M(61)$  is prime, finally disproving the Mersenne conjecture. Powers in the early 1900s showed that  $M(89)$  and  $M(107)$  are prime, both missed by Mersenne. By 1947, it was known that the correct list is  $2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, 127$ , so Mersenne had five errors in his list: 67 and 257 should have been removed, and 61, 89, and 107 added. By late 2001, 39 Mersenne primes were known, the five largest having been found by massive distributed computing efforts through the Great Internet Mersenne Primes Search (GIMPS) project. The largest of these is
